Date of Revision:  
October 23, 2018

Control No.: 211038

**Pr TOBRAMYCIN INJECTION, USP**  
**10 mg tobramycin / mL**  
**40 mg tobramycin / mL**

**Pr TOBRAMYCIN FOR INJECTION, USP**  
**1.2 g tobramycin / vial**

**THERAPEUTIC CLASSIFICATION**  
**Antibiotic**

**ACTION**

Like other aminoglycosides, tobramycin binds to proteins on the 30S ribosome of bacteria thereby inhibiting protein synthesis, particularly the initiation step. Inhibition of protein synthesis is not a lethal event in bacteria as is destruction of the cell envelope. Nevertheless, the aminoglycosides bind so strongly to their receptors that the binding is essentially irreversible and the end result is death of the bacterial cell.

Aminoglycosides also cause misreading of the genetic code, so that incorrect amino acids are incorporated into the proteins of the bacterial cell. This mechanism is probably less important than inhibition of protein synthesis in killing cells.

After intravenous administration, serum concentrations of tobramycin are similar to those following intramuscular injection, and are dose related. The serum half-life is about 2 hours for patients with normal renal function and ranges from 5 to 47 hours for patients with impaired renal function. Tobramycin is eliminated exclusively by glomerular filtration. Tobramycin is not protein bound to any degree.

**INDICATIONS**

Tobramycin Injection, USP and Tobramycin for Injection, USP may be indicated for the treatment of the following infections when caused by susceptible organisms: septicemia, complicated and recurrent urinary tract infections, lower respiratory infections, serious skin and soft tissue infections including burns and peritonitis, and central nervous system infections caused by organisms resistant to antibiotics usually considered efficacious in these infections.

Tobramycin is usually active against most strains of the following organisms *in vitro* and in clinical infections:

- *Pseudomonas aeruginosa*
- *Proteus* sp. (indole-positive and indole-negative), including *Proteus mirabilis*, *Morganella morganii*, *Providencia rettgeri*, and *Proteus vulgaris*
- *Escherichia coli*

- *Klebsiella-Enterobacter-Serratia* group
- *Citrobacter* sp.
- *Providencia* sp.
- Staphylococci, including *Staphylococcus aureus* (coagulase-positive and coagulase-negative).

Tobramycin Injection, USP and Tobramycin for Injection, USP may be considered in serious staphylococcal infections when penicillin or other potentially less toxic drugs are contraindicated and when bacterial susceptibility testing and clinical judgment indicate its use.

To reduce the development of drug-resistant bacteria and maintain the effectiveness of Tobramycin Injection, USP, Tobramycin for Injection, USP and other antibacterial drugs, Tobramycin Injection, USP and Tobramycin for Injection, USP should be used only to treat infections that are proven or strongly suspected to be caused by susceptible bacteria. When culture and susceptibility information are available, they should be considered in selecting or modifying antibacterial therapy. In the absence of such data, local epidemiology and susceptibility patterns may contribute to the empiric selection of therapy.

Appropriate sensitivity studies should be performed to determine the susceptibility of the causative organism to Tobramycin. Clinical judgment and anticipated bacteriological findings may permit the start of therapy before results of susceptibility studies are obtained.

Note: If susceptibility tests show that the causative organism is resistant to tobramycin, other appropriate therapy should be instituted.

## CONTRAINDICATIONS

Tobramycin is contraindicated in patients with known hyper-sensitivity to tobramycin or any other aminoglycoside. Cross-allergenicity to other aminoglycosides has been established.

## WARNINGS

Patients treated with tobramycin or other aminoglycosides should be under close clinical observation because these drugs have an inherent potential for causing ototoxicity and nephrotoxicity.

Both vestibular and auditory toxicity can occur. Impairment of eighth-nerve function is most likely in patients with pre-existing renal damage, especially if the drug is administered for longer periods or in higher doses than those recommended.

Patients with known or suspected impairment of renal function should be under close clinical observation, and renal and eighth-nerve function should be monitored during therapy.

Renal and eighth-nerve function monitoring is also recommended during the treatment of patients in whom renal function is initially normal, but in whom oliguria or evidence of nitrogen retention (increasing BUN, NPN, or creatinine) develops during therapy. Evidence of developing impairment in renal, vestibular, and/or auditory function requires careful observance of dosage adjustments (see Table 1). Discontinuation of the drug may be indicated.

Peak and trough serum concentrations of aminoglycosides should be monitored periodically during therapy to assure adequate levels and to avoid potentially toxic levels. Prolonged serum concentrations above 12 mg/L should be avoided. Rising trough levels (above 2 mg/L) may indicate tissue accumulation. Such accumulation, excessive peak concentrations, advanced age, and cumulative dose may contribute to ototoxicity and nephrotoxicity.

Careful monitoring is required with concurrent and/or sequential use of other potentially neurotoxic and/or nephrotoxic drugs, particularly other aminoglycosides (e.g., amikacin, streptomycin, neomycin, kanamycin, gentamicin, and paromomycin), amphotericin B, cephaloridine, viomycin, polymyxin B, colistin, cisplatin, and vancomycin. Other factors that may increase patient risk are advanced age and dehydration.

Tobramycin should not be used concurrently with potent diuretics because some diuretics themselves cause ototoxicity.

Tobramycin sulfate contains sodium bisulfite, a sulfite that may cause allergic-type reactions, including anaphylactic symptoms and life-threatening or less severe asthmatic episodes, in certain susceptible people.

### **Gastrointestinal**

#### ***Clostridium Difficile*-Associated Disease**

*Clostridium difficile*-associated disease (CDAD) has been reported with use of many antibacterial agents, including Tobramycin. CDAD may range in severity from mild diarrhea to fatal colitis. It is important to consider this diagnosis in patients who present with diarrhea, or symptoms of colitis, pseudomembranous colitis, toxic megacolon, or perforation of colon subsequent to the administration of any antibacterial agent. CDAD has been reported to occur over 2 months after the administration of antibacterial agents.

Treatment with antibacterial agents may alter the normal flora of the colon and may permit overgrowth of *Clostridium difficile*. *Clostridium difficile* produces toxins A and B, which contribute to the development of CDAD. CDAD may cause significant morbidity and mortality. CDAD can be refractory to antimicrobial therapy.

If the diagnosis of CDAD is suspected or confirmed, appropriate therapeutic measures should be initiated. Mild cases of CDAD usually respond to discontinuation of antibacterial agents not directed against *Clostridium difficile*. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an antibacterial agent clinically effective against *Clostridium difficile*. Surgical evaluation should be instituted as clinically indicated, as surgical intervention may be required in certain severe cases.

### **Pregnancy**

Safety for use in pregnancy has not been established. Animal and human studies have demonstrated that there is a maternal-fetal transfer of tobramycin. No reports to date have revealed teratogenic effects in humans. However, one study in guinea pigs using high doses (50 to 100 mg/kg) in the last four weeks of pregnancy revealed a low incidence of ototoxicity in the newborn. (See Teratology and Reproduction)

### **Susceptibility/Resistance**

#### *Development of Drug-Resistant Bacteria*

Prescribing Tobramycin Injection, USP and Tobramycin for Injection, USP in the absence of a proven or strongly suspected bacterial infection is unlikely to provide benefit to the patient and risks the development of drug-resistant bacteria.

## **PRECAUTIONS**

Neuromuscular block and respiratory paralysis have been reported in cats receiving very high doses of tobramycin (40 mg/kg). The possibility that these phenomena may occur in man should be considered if tobramycin is administered to patients who are also receiving general anesthesia and/or neuromuscular blocking agents such as succinylcholine and tubocurarine, or in patients with myasthenia gravis or Parkinson's disease.

Tobramycin should be used with caution in premature and neonatal infants because of their renal immaturity and the resulting prolongation of serum half-life of the drug.

If overgrowth of non-susceptible organisms occurs, appropriate therapy should be initiated, and if necessary, the drug withdrawn.

Although not indicated for intraocular and/or subconjunctival use, macular necrosis following this type of injection of aminoglycosides, including tobramycin, has been reported.

## **ADVERSE REACTIONS**

### **Nephrotoxicity**

Renal function changes, as shown by rising BUN, NPN, and serum creatinine, and by oliguria, have been reported, especially in patients with a history of renal impairment who were treated for longer periods or with doses higher than those recommended.

### **Neurotoxicity**

Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported, especially in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears, and high-frequency hearing loss.

Other adverse reactions that have been reported, and may be associated with tobramycin therapy, include increased serum transaminases (SGOT, SGPT), increased alkaline phosphatase and

increased serum bilirubin; anemia, granulocytopenia, and thrombocytopenia; fever, rash, exfoliative dermatitis, itching, urticaria, nausea, vomiting, diarrhea, headache, and lethargy. Local reaction at the site of injection has been reported.

## **OVERDOSAGE**

For management of a suspected drug overdose, contact your regional Poison Control Centre immediately.

### **Signs and Symptoms**

The severity of the signs and symptoms following a tobramycin overdose are dependent on the dose administered, the patient's renal function, state of hydration, and age, and whether or not other medications with similar toxicities are being administered concurrently. Toxicity may occur in patients treated more than 10 days, given more than 5 mg/kg/day, in children given more than 7.5 mg/kg/day, or in patients with reduced renal function whose dose has not been appropriately adjusted.

Nephrotoxicity following the parenteral administration of an aminoglycoside is most closely related to the area under the curve of the serum concentration versus time graph. Nephrotoxicity is more likely if trough blood concentrations fail to fall below 2 mg/L and is also proportional to the average blood concentration. Patients who are elderly, have abnormal renal function, are receiving other nephrotoxic drugs, or are volume depleted, are at greater risk for developing acute tubular necrosis. Auditory and vestibular toxicities have been associated with aminoglycoside overdose. These toxicities occur in patients treated longer than 10 days, in patients with abnormal renal function, in dehydrated patients, or in patients receiving medications with additive auditory toxicities. These patients may not have signs or symptoms or may experience dizziness, tinnitus, vertigo, and a loss of high-tone acuity as ototoxicity progresses. Ototoxicity signs and symptoms may not begin to occur until long after the drug has been discontinued.

Neuromuscular blockade or respiratory paralysis may occur following administration of aminoglycosides. Neuromuscular blockade, prolonged respiratory paralysis, and respiratory failure may occur more commonly in patients with myasthenia gravis or Parkinson's disease. Prolonged respiratory paralysis may also occur in patients receiving decamethonium, tubocurarine, or succinylcholine. If neuromuscular blockade occurs, it may be reversed by the administration of calcium salts but mechanical assistance may be necessary.

If tobramycin were ingested, toxicity would be less likely because aminoglycosides are poorly absorbed from an intact gastrointestinal tract.

### **Treatment**

The initial management in a tobramycin overdose is to assess respiration and, if necessary, to establish an airway, and ensure oxygenation and ventilation. Resuscitative measures should be initiated promptly if respiratory paralysis occurs.

Patients who have received an overdose of tobramycin and have normal renal function should be carefully hydrated to maintain a urine output of 3 to 5 mL/kg/hr. Fluid balance, creatinine clearance, and tobramycin plasma levels should be carefully monitored until the serum tobramycin level falls below 2 mg/L.

Patients in whom the elimination half-life is greater than 2 hours or whose renal function is abnormal may require more aggressive therapy. In such patients, hemodialysis may be beneficial.

## **DOSAGE AND ADMINISTRATION**

Tobramycin Injection, USP and Tobramycin for Injection, USP may be given intramuscularly or intravenously. The intravenous dose is the same as the intramuscular dose.

### **Dosage**

#### **Adults:**

The recommended dosage for patients with normal renal function is 1 mg/kg every eight hours, for a total of 3 mg/kg/day. Mild to moderate infections of the lower urinary tract have responded to doses of 2 to 3 mg/kg/day administered once daily. When renal tissue is involved or in serious infections, especially when there are signs of systemic involvement, two or three equally divided doses are recommended.

The usual dosage for patients weighing more than 60 kg is 80 mg (2 mL) every eight hours. For patients weighing 60 kg or less, the usual dosage is 60 mg (1.5 mL) every eight hours.

In patients with life-threatening infections, dosages up to 5 mg/kg/day may be administered in three or four equal doses. This dosage should be reduced to 3 mg/kg/day as soon as clinically indicated. To prevent increased toxicity due to excessive blood levels, dosage should not exceed 5 mg/kg/day unless serum levels are monitored.

#### **Children:**

6 to 7.5 mg/kg/day in 3 or 4 equally divided doses.

#### **Neonates (one week of age or less):**

Dosage up to 4 mg/kg/day may be administered in two equal doses every twelve hours (see PRECAUTIONS).

The usual duration of treatment is seven to ten days. A longer course of therapy may be necessary in difficult and complicated infections. Monitoring of renal, auditory, and vestibular functions is advisable in these cases because neurotoxicity is more likely to occur when treatment is extended for longer than ten days.

#### **Patients with Impaired Renal Function:**

Serum tobramycin concentrations should be monitored during therapy.

Following a loading dose of 1 mg/kg, subsequent dosage in these patients must be adjusted, either with lower doses administered at eight-hour intervals or with normal doses at prolonged intervals (see Table 1). Both regimens should be based on the BUN, the serum creatinine or the creatinine clearance of the patient, because these values correlate with the half-life of tobramycin.

**Adjusted Dose at Eight-Hour Intervals (Regimen I):**

An appropriately reduced dosage range can be found in Table 1 for any patient for whom the BUN, creatinine clearance or serum creatinine values are known. The choice of dose within the indicated range should be based on the severity of the infection, the sensitivity of the pathogen, and individual patient considerations, especially renal function.

**Adjusted Intervals Between Fixed Doses (Regimen II):**

Recommended intervals between doses are given in Table 1. As a general rule, the interval in hours can be determined by multiplying the patient's serum creatinine level by six.

**Table 1: Two Maintenance Regimens Based on Renal Function and Body Weight Following a Loading Dose of 1 mg/kg\***

| Renal Function <sup>+</sup> |                              | REGIMEN I                          |            | OR                                     | REGIMEN II        |
|-----------------------------|------------------------------|------------------------------------|------------|--|-------------------|
|                             |                              | Adjusted Doses of 8-Hour Intervals |            | Adjusted Intervals Between Fixed Doses |                   |
| Serum Creatinine<br>mcmol/L | Creatinine Clearance<br>mL/s | Weight                             |            | Weight/Dose                            |                   |
|                             |                              | 50 - 60 kg                         | 60 - 80 kg | 50 - 60 kg: 60 mg                      | 60 - 80 kg: 80 mg |
| ≤ 115                       | ≥ 1.17                       | 60 mg                              | 80 mg      | q 8 h                                  |                   |
| 125 - 170                   | 1.15 - 0.67                  | 30 - 60 mg                         | 50 - 80 mg | q 12 h                                 |                   |
| 175 - 290                   | 0.65 - 0.33                  | 20 - 25 mg                         | 30 - 45 mg | q 18 h                                 |                   |
| 300 - 470                   | 0.32 - 0.17                  | 10 - 18 mg                         | 15 - 24 mg | q 24 h                                 |                   |
| 475 - 660                   | 0.15 - 0.08                  | 5 - 9 mg                           | 7 - 12 mg  | q 36 h                                 |                   |
| ≥ 670                       | ≤ 0.07                       | 2.5 - 4.5 mg                       | 3.5 - 6 mg | q 48 h <sup>++</sup>                   |                   |

\* For life-threatening infections, dosages 50% above those recommended may be used. The dosage should be reduced as soon as possible after improvement is noted.

<sup>+</sup> If used to estimate degree of impairment, serum creatinine concentrations should reflect a steady state of renal azotemia.

<sup>++</sup> When dialysis is not being performed.

Both of these regimens are suggested as guides to be used when serum levels of tobramycin cannot be measured directly. The appropriate dosage schedules derived from either regimen should be used in conjunction with careful clinical and laboratory observations of the patient and should be modified as necessary.

**Dosage in Moderate to Marked Obesity:**

The appropriate dose may be calculated by using the patient's estimated lean body weight plus 40% of the excess as the basic weight on which to figure mg/kg.

**Administration**

Tobramycin may be administered by the intramuscular or intravenous route.

**Intravenous Administration:**

This route is recommended when the intramuscular route is not feasible, e.g., in the presence of shock, hematologic disorders, severe burns, or reduced muscle mass.

The concentration of tobramycin in solution should not normally exceed 1 mg/mL for either adults or children. The solution should be infused over a period of 20 to 60 minutes. When it is necessary to restrict the volume of solution infused, a more concentrated solution may be used, however, it is important that the infusion time exceeds five minutes to prevent excessively high serum concentrations. A volume control set is recommended for this administration.

Note: Tobramycin Injection, USP and Tobramycin for Injection, USP should not be physically premixed with other drugs but should be administered separately according to the recommended dose and route.

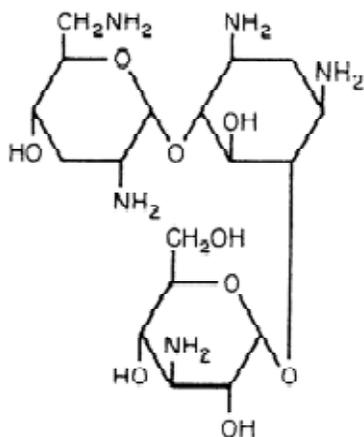

## PHARMACEUTICAL INFORMATION

### Drug Substance

**Proper Name:** Tobramycin

**Chemical Name:** *O*-3-Amino-3-deoxy- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 4)-*O*-[2,6-diamino-2,3,6-trideoxy- $\alpha$ -D-ribo-hexopyranosyl-(1 $\rightarrow$ 6)]-2-deoxystreptamine

### **Structural Formula:**

**Molecular Formula:**  $C_{18}H_{37}N_5O_9$

**Molecular Mass:** 467.54 g/mol

**Description:** Tobramycin is a white to off-white hygroscopic powder. It is a basic aminocyclitol aminoglycoside, freely soluble in water. A 10% solution in water has a pH of 9 to 11. Melting range = 172 °C – 178 °C.

### DOSAGE FORM

#### Composition

**Tobramycin Injection, USP 10 mg / mL:**

Each mL of solution contains: tobramycin sulfate equivalent to tobramycin 10 mg, 0.1 mg edetate disodium, 5 mg phenol, 3.2 mg sodium metabisulfite in water for injection. May contain sodium hydroxide and/or sulfuric acid for pH adjustment.

**Tobramycin Injection, USP 40 mg / mL:**

Each mL of solution contains: tobramycin sulfate equivalent to tobramycin 40 mg, 0.1 mg edetate disodium, 5 mg phenol, 3.2 mg sodium metabisulfite in water for injection. May contain sodium hydroxide and/or sulfuric acid for pH adjustment.

**Tobramycin for Injection, USP 1.2 g / vial:**

Tobramycin for Injection, USP Pharmacy Bulk Vials contain lyophilized tobramycin sulfate equivalent to 1.2 g tobramycin with no preservatives.

**RECONSTITUTION**

**Solutions for Reconstitution**

Sterile Water for Injection

**Table 2: Reconstitution Table for Pharmacy Bulk Vial**

| <b>Vial Size</b>                  | <b>Volume to be added to vial</b> | <b>Approximate Available Volume</b> | <b>Approximate Average Concentration</b> |
|-----------------------------------|-----------------------------------|-------------------------------------|--|
| 1.2 g Powder (Pharmacy Bulk Vial) | 30 mL                             | 31.0 mL                             | 40 mg / mL                               |

Shake well until dissolved.

The Pharmacy Bulk Vial is intended only for intravenous infusion (by single puncture for multiple dispensing).

**Solutions for Intravenous Infusion**

5% Dextrose in Water

0.9% Sodium Chloride Injection

**Dilution of Tobramycin Injection, USP**

| <b>Concentration</b> | <b>Tobramycin</b>     | <b>Volume of Diluent</b> |
|----------------------|-----------------------|--------------------------|
| 0.2 mg / mL          | 20 mg / 2 mL (1 vial) | 100 mL                   |
| 0.4 mg / mL          | 20 mg / 2 mL (1 vial) | 50 mL                    |
| 0.8 mg / mL          | 80 mg / 2 mL (1 vial) | 100 mL                   |
| 1.6 mg / mL          | 80 mg / 2 mL (1 vial) | 50 mL                    |

## STABILITY OF SOLUTION

The Pharmacy Bulk Vial is intended for multiple dispensing for intravenous use employing a single puncture. Following reconstitution, the solution should be dispensed and diluted for use within 8 hours. Any unused reconstituted solution should be discarded after 8 hours.

Reconstituted solution of Tobramycin for Injection diluted with any of the solutions for intravenous infusion listed above in concentration range of 1 mg/mL to 0.2 mg/mL should be used within 24 hours if kept at room temperature and 36 hours if stored under refrigeration.

Tobramycin Injection, USP diluted with either of the solutions for intravenous infusion listed above in a concentration range of 0.2 mg/mL to 1.6 mg/mL should be used within twenty-four hours if kept at room temperature.

As with all parenteral drug products, intravenous admixture should be inspected visually for clarity, particulate matter, precipitation, discolouration and leakage prior to administration whenever solution and container permit. Discard unused portion.

## STORAGE AND STABILITY

Tobramycin for Injection, USP should be stored at controlled room temperatures below 30 °C.

Tobramycin for Injection, USP requires no refrigeration.

Tobramycin Injection, USP should be stored at controlled room temperature (15 °C to 30 °C). Multiple-dose vials. Discard unused portion 28 days after initial puncture.

## SPECIAL INSTRUCTIONS

- Pharmacy Bulk Vials contain no preservatives. Care must be taken to minimize the potential for inadvertent introduction of microorganisms during manipulation in the hospital environment.
- The availability of the Pharmacy Bulk Vial is restricted to hospitals with a recognized intravenous admixture program.

## AVAILABILITY OF DOSAGE FORMS

Tobramycin is available in the following forms and package sizes:

**C300502**      **Tobramycin Injection, USP, 10 mg / mL:** Each mL of solution contains: tobramycin sulfate equivalent to tobramycin 10 mg. Rubber stoppered vials of 2 mL for multiple use, packaged in cartons of 25 vials.

- C300602**     **Tobramycin Injection, USP, 40 mg / mL:** Each mL of solution contains: tobramycin sulfate equivalent to tobramycin 40 mg. Rubber stoppered vials of 2 mL for multiple use, packaged in cartons of 25 vials.
- C300604**     **Tobramycin Injection, USP, 40 mg / mL:** Each mL of solutions contains: tobramycin sulfate equivalent to tobramycin 40 mg. Rubber stoppered vials of 4 mL for multiple use, packaged in cartons of 25 vials.
- C300630**     **Tobramycin Injection, USP, 40 mg / mL:** Each mL of solution contains: tobramycin sulfate equivalent to tobramycin 40 mg. Rubber stoppered vials of 30 mL for multiple use, packaged in cartons of 10 vials.
- C300351**     **Tobramycin for Injection, USP, 1.2 g / vial:** Each vial contains lyophilized tobramycin sulfate equivalent to 1.2 g of tobramycin, in 50 mL Pharmacy Bulk Vial, packaged in cartons of 6 vials.

TOBRAMYCIN FOR INJECTION PHARMACY BULK VIAL DOES NOT CONTAIN ANY PRESERVATIVES.

Vial stoppers do not contain natural rubber latex.

## MICROBIOLOGY

*In vitro* tests demonstrate that tobramycin is bactericidal and that it acts by inhibiting the synthesis of protein in bacterial cells.

Tobramycin is active against most strains of the following organisms:

- *Pseudomonas aeruginosa*
- *Proteus* sp. (indole-positive and indole-negative), including *Proteus mirabilis*, *Morganella morganii*, *Providencia rettgeri*, and *Proteus vulgaris*
- *Escherichia coli*
- *Klebsiella-Enterobacter-Serratia* sp.
- *Citrobacter* sp.
- *Providencia* sp.
- Staphylococci, including *Staphylococcus aureus* (coagulase-positive and coagulase-negative).

Although most strains of enterococci demonstrate *in vitro* resistance, some strains in this group are susceptible. *In vitro* studies have shown that an aminoglycoside combined with an antibiotic which interferes with cell-wall synthesis affects some enterococcal strains synergistically. The combination of penicillin G and tobramycin results in a synergistic bactericidal effect *in vitro* against certain strains of *Enterococcus faecalis* (formerly *Streptococcus faecalis*). However, this combination is not synergistic against other closely related organisms, e.g., *Enterococcus faecium* (formerly *Streptococcus faecium*). Speciation of enterococci alone cannot be used to

predict susceptibility. Susceptibility testing and tests for antibiotic synergism are therefore required.

**Table 3: *In Vitro* Susceptibility of Microorganism to Tobramycin (Cumulative Percent of Strains inhibited in Broth or Agar-Dilution Studies)**

| I-----MIC mg/L-----I                         |                |             |             |             |            |             |            |            |            |             |     |
|--|----------------|-------------|-------------|-------------|------------|-------------|------------|------------|------------|-------------|-----|

\* Inoculum did not exceed  $10^5$  organisms per mL in broth.

### **Susceptibility Plate Tests**

If the Bauer-Kirby-Sherris-Turck method of disk susceptibility testing is used (Am. J. Clin. Pathol., 45:493, 1966), a disk containing 10 mcg tobramycin should give a zone of inhibition of at least 15 mm when tested against a tobramycin susceptible bacterial strain and a zone of inhibition of 13 to 14 mm against strains of intermediate susceptibility, and a zone of inhibition of 12 mm or less against resistant organisms. The minimum inhibitory concentration correlates are  $\leq 4$  mg/L for susceptibility and  $\geq 8$  mg/L for resistance.

## **PHARMACOLOGY**

### **Human Pharmacology**

Peak serum concentrations of tobramycin occur between thirty and 130 minutes after intramuscular administration.

**Table 4: Serum Concentrations After Single Intramuscular Doses**

| <b>SERUM CONCENTRATION (mg/L)</b> |                |              |              |              |              |
|-----------------------------------|----------------|--------------|--------------|--------------|--------------|
| <b>DOSE</b>                       | <b>1/2 hr.</b> | <b>1 hr.</b> | <b>2 hr.</b> | <b>4 hr.</b> | <b>8 hr.</b> |
| 25 mg                             | 1.14           | 0.8          | 0.56         | 0.26         | 0.01         |
| 50 mg                             | 2.09           | 1.95         | 1.26         | 0.56         | 0.1          |
| 75 mg                             | 2.71           | 2.68         | 1.86         | 0.9          | 0.2          |
| 100 mg                            | 2.95           | 3.25         | 2.61         | 1.36         | 0.41         |
| 200 mg                            | 9.63           | 8.99         | 7.7          | 4.33         | 0.94         |

In patients with normal renal function, tobramycin administered every eight hours does not accumulate in the serum. A serum half-life of about 2 hours was reported for patients with normal renal function while in patients with impaired renal function serum half-life of the drug ranged from 5 to 47 hours.

Dosage for such patients must, therefore, be adjusted accordingly (see DOSAGE AND ADMINISTRATION).

After intravenous administration, serum concentrations are similar to those following intramuscular injection, and are dose related.

**Table 5: Intravenous Dose Infused Over 30 – 45 Minutes**

| <b>SERUM CONCENTRATION (mg/L)</b> |                |                |              |              |              |              |
|-----------------------------------|----------------|----------------|--------------|--------------|--------------|--------------|
| <b>DOSE</b>                       | <b>1/4 hr.</b> | <b>1/2 hr.</b> | <b>1 hr.</b> | <b>2 hr.</b> | <b>4 hr.</b> | <b>6 hr.</b> |
| 1 mg/kg                           | 3.8            | 5.5            | 3.85         | 2.38         | 1.04         | 0.52         |
| 1.5 mg/kg                         | 4.85           | 6.02           | 5.28         | 2.96         | 1.72         | 0.9          |

Pediatric studies indicate that although the serum half-life in neonates was found to be 2 or 3 times longer than in adults, no accumulation of tobramycin occurred even after multiple doses of 4 mg/kg/day.

Tobramycin is eliminated almost exclusively by glomerular filtration; renal clearance is similar to that of endogenous creatinine. Ultrafiltration studies demonstrate that practically no serum protein binding occurs. In patients with normal renal function, up to 84 percent of the dose is recoverable from the urine in eight hours and up to 93 percent in twenty-four hours.

Peak urine concentrations up to 100 mg/L have been observed after the intramuscular injection of a single dose of 1 mg/kg. After several days of treatment, the amount of tobramycin excreted in the urine approaches the daily dose administered.

An inverse relationship exists between half-life and creatinine clearance, and the dosage schedule should be adjusted according to the degree of renal impairment. In patients undergoing hemodialysis, 25 to 70 percent of the administered dose may be removed, depending upon the duration of hemodialysis. Peritoneal dialysis was considered to be less efficient.

Tobramycin can be detected in tissues and body fluids after parenteral administration. Concentrations in bile ordinarily have been low, which suggests minimum biliary excretion. Tobramycin has been found in low and unpredictable concentrations in the cerebrospinal fluid following parenteral administration and would be inadequate against many gram-negative organisms causing meningitis. It has also been found in sputum and in abscess fluids though possibly in non-therapeutic concentrations. Tobramycin crosses the placental membranes producing in one study a fetal serum half-life of 3.2 hours and a peak serum concentration of 1.2 mg/L.

## TOXICOLOGY

### Acute Toxicity

The acute toxicity of parenterally administered tobramycin was related to immediate CNS effects. Death often occurred within a few minutes after an intravenous dose and 20 minutes to 2 hours after subcutaneous administration. In a few rats and one guinea pig, delayed deaths were attributed to renal injury.

The intravenous LD<sub>50</sub> values ranged from 53 to 107 mg/kg for mice and 131 to 134 mg/kg for rats; while the subcutaneous LD<sub>50</sub> values were 416 to 484 mg/kg for mice and 928 to 1028 mg/kg for rats.

Tobramycin was no more toxic in newborn rats than in rats of 5 to 6 weeks of age, but it was slightly more toxic to 3 month old animals.

Two dogs were treated with subcutaneous doses of 100 and 200 mg/kg. No effect was observed with the 100 mg dose. Retching and tremors occurred after the administration of the 200 mg dose. The animals appeared normal after 3 hours. Two dogs tolerated single intravenous doses of 100 mg/kg with emesis as the only observed sign of toxicity.

Two cats received subcutaneous doses of 200 mg/kg of tobramycin which produced marked CNS effects that persisted for more than 5 hours. Both animals appeared normal on the following day. An intravenous dose of 50 mg/kg in three cats produced a short-term ataxia. A dosage of 100 mg/kg caused convulsions and death.

### Subacute Toxicity

**Rats:** In a study using 10 animals/sex/dose, rats given 30 daily subcutaneous doses of 30, 60, or 120 mg/kg of tobramycin survived, with the exception of 1 of 20 of the 120 mg/kg dosage group. There were no significant changes in appearance or behavior. The 120 mg/kg regimen caused a slight retardation of growth in the females.

A slight renal toxicity was noted at all doses by virtue of an increase in SGOT, increased renal weights, and the histologic finding of a slight to moderate regeneration of renal cortical tubular epithelium. These effects were dose dependent.

In a similar study, rats tolerated 14 daily intravenous doses of 20 - 80 mg/kg of tobramycin with no adverse effects other than those associated with CNS effects after rapid injection. Six of 10 of the animals of the 80 mg/kg group died shortly after tobramycin administration. The hematologic and blood chemistry data of the surviving animals were unaffected. The relative renal weights of the tobramycin-dosed animals were significantly greater than control. The effect was dose dependent.

No drug-related tissue changes were noted in rats of the 20 mg/kg group. A slight regeneration of renal cortical tubular epithelium was detected in 1 of 20 animals given 40 mg/kg and most of those given 80 mg/kg. It was concluded that the only hazard in administration of tobramycin by the intravenous route rather than by the subcutaneous route is that a too rapid intravenous injection can cause convulsions and death.

**Dogs:** A study using 4 dogs for each daily intramuscular dose was carried out for 28 days. The appearance, behaviour, hematology, and blood chemistry were unaffected by doses of 3.75 to 15 mg/kg. Histologic examination of the tissue revealed that a slight renal injury, as evidenced by the finding of a mild regeneration of the cortical tubular epithelium, had occurred at the upper dose.

In a further study with 4 dogs, a daily dose of 30 mg/kg was tolerated for 2 weeks with no apparent ill effects; but thereafter, anorexia, weight loss, hypoactivity, and a general CNS depression were noted. Two animals were killed during the fourth week because of morbidity. Renal tubular necrosis accompanied by regeneration of the tubular epithelium was noted in all animals of the 30 mg/kg group.

Dogs had a reduced tolerance for tobramycin dosage regimens of longer duration. In a study using 2 dogs/sex/dose for 90 days, a daily intramuscular dose of 3.75 or 7.5 mg/kg of tobramycin caused no changes in appearance, behavior, or body weight, but 2 of 4 dogs on the 7.5 mg/kg dose had a mild degree of renal cortical tubular epithelial regeneration or a mild reparative nephrosis.

A daily dose of 15 mg/kg of tobramycin was well tolerated by 2 of 4 dogs. The other 2 dogs of this group had marked appetite suppression, weight loss, and marked elevations in BUN and SGOT. One of these dogs became deaf on day 49. This dog also showed evidence of tobramycin accumulation. A mild to moderate reparative nephrosis and inflammatory reactions at the injection sites represented the only histologic evidence of tobramycin injury.

The daily intravenous administration of 7.5, 15 or 30 mg/kg of tobramycin for 2 dogs/sex/dose over 14 days caused no changes in appearance or behavior except for a single emetic episode in one dog of the 30 mg/kg group. Blood serum concentrations of tobramycin one hour after intravenous injection were similar to those found one hour after intramuscular administration.

The hematologic and blood chemistry parameters were not altered significantly. A slight to moderate proteinuria was detected in one or two dogs of each dosage regimen, and a slight glucosuria occurred in one animal of the 15 mg/kg group. There was no histologic evidence of tissue injury. It seems probable, however, on the basis of the results of intramuscular administration of similar doses, that renal injury would occur with more prolonged intravenous dosage.

**Cats:** In a study using 2 animals/sex/dose, cats were given daily subcutaneous doses of 25 or 50 mg/kg. The 25 mg/kg dose was tolerated by 4 cats for 65 doses with no apparent vestibular injury. Haemorrhagic cystitis and urinary tract blockage due to urolithiasis in one male cat were considered unrelated to the drug, but co-existent renal cortical tubular necrosis with epithelial regeneration in the same cat were probably drug-related. One other cat had slight regeneration of renal cortical tubular epithelium. The 50 mg/kg/day dosage was poorly tolerated by all 4 cats. One cat was sacrificed after 25 doses, and another after 40 doses, because of poor physical condition. Tobramycin administration was terminated for the other 2 cats of this group on day 40. All 4 animals had severe vestibular injury. The 2 cats sacrificed during treatment had moderate renal tubular necrosis. A lack of histological evidence of renal injury in the 2 cats that were sacrificed 34 days after a 40 dose treatment, plus the finding of regenerative cortical tubular epithelium in animals killed during treatment suggested that moderate renal injury, occurring as the result of tobramycin administration, may be reversible.

In a second study, 6 cats received tobramycin in a dosage of 35 mg/kg/day causing a marked reduction in PRN times in all six cats within 20 to 47 days.

**Guinea Pigs:** In a study using guinea pigs, a daily 50 mg/kg dose of tobramycin had no effect on growth or on auditory function in a 4-week period. A 100 mg/kg dose caused a 25% retardation of growth, as compared with controls. No hearing impairment was noted at 2 weeks, but some loss was detected at 4 weeks.

In a further study, daily doses of 150 to 200 mg/kg markedly depressed growth and was lethal to 40% of the animals within 6 weeks. Cochlear injury that occurred in 40% of the surviving animals was verified by electrophysiologic and histopathologic methods.

### **Teratology and Reproduction**

Daily subcutaneous administration of tobramycin given in 50 and 100 mg/kg doses to rats (30 animals/sex/dose) during all phases of the reproductive cycle, had no adverse effect on fertility or reproductive performance, nor did it affect the progeny.

In a further study, pregnant rats were given subcutaneous doses of 50 and 100 mg/kg of tobramycin from gestation days 14 through 20. Reparative nephrosis was detected in 6 of 25 of the 50 mg/kg group and 22 of 25 of the 100 mg/kg group at necropsy. There was no adverse effect on reproduction indices, nor on the growth of the progeny.

Daily subcutaneous doses of 20 or 40 mg/kg of tobramycin were given to pregnant rabbits (15 animals/dose) during organogenesis and early fetal development (gestation days 6 – 18).

A marked anorexia and weight loss occurred in several animals; 3 of the 20 mg/kg group and 13 of the 40 mg/kg group died or aborted prior to gestation day 28. Drug-induced renal injury was evident in most of the animals that received the antibiotic. Fetal development appeared normal in all of the dams, including those that died or aborted. No drug-related abnormalities were detected in any of the progeny. It was concluded that daily subcutaneous doses as great as 40 mg/kg were not teratogenic in the rabbit, despite marked maternal toxicity.

A 25 to 200 mg/kg daily dose of tobramycin to mice during the period of organogenesis produced no embryocidal or teratogenic effect.

Tobramycin doses of 100 mg/kg/day administered to pregnant guinea pigs in early gestation, from the beginning of the second week to the end of the fifth week, resulted in hearing loss and histological damage to the six mothers. The litters born to these females, however, showed no hearing loss or damage to the inner ear. In contrast, when tobramycin was administered at 50 or 100 mg/kg daily to females in the terminal four weeks of gestation, one of eighteen newborn animals had pinna reflex loss at 20,000 Hz and four of thirty-eight had unilateral, incomplete loss of outer hair cells at the basal end of the cochlea.

## READ THIS FOR SAFE AND EFFECTIVE USE OF YOUR MEDICINE

### PATIENT MEDICATION INFORMATION

#### <sup>Pr</sup> **Tobramycin Injection, USP** <sup>Pr</sup> **Tobramycin for Injection, USP**

Read this carefully before you start taking Tobramycin Injection, USP and Tobramycin for Injection, USP and each time you get a refill. This leaflet is a summary and will not tell you everything about this drug. Talk to your healthcare professional about your medical condition and treatment and ask if there is any new information about Tobramycin Injection, USP and Tobramycin for Injection, USP.

#### **What are Tobramycin Injection, USP and Tobramycin for Injection, USP used for?**

Tobramycin Injection, USP and Tobramycin for Injection, USP are used to treat certain bacterial infections:

- of the chest and lungs (lower respiratory tract)..
- in the blood.
- of the kidneys and urinary bladder (urinary tract).
- in the brain, spinal cord and nerves (central nervous system).
- of the skin and muscle.

Antibacterial drugs like Tobramycin Injection, USP and Tobramycin for Injection, USP treat only bacterial infections. They do not treat viral infections such as the common cold. Although you may feel better early in treatment, Tobramycin Injection, USP and Tobramycin for Injection, USP should be used exactly as directed. Misuse or overuse of Tobramycin Injection, USP and Tobramycin for Injection, USP could lead to the growth of bacteria that will not be killed by Tobramycin Injection, USP and Tobramycin for Injection, USP (resistance). This means that Tobramycin Injection, USP and Tobramycin for Injection, USP may not work for you in the future.

#### **How does Tobramycin Injection, USP and Tobramycin for injection, USP work?**

Tobramycin is an antibiotic. It works by killing or slowing the growth of certain types of bacteria that cause the infection

#### **What are the ingredients in Tobramycin Injection, USP and Tobramycin for Injection, USP?**

##### **Tobramycin Injection:**

**Medical ingredients:** Tobramycin

**Non-medical ingredients:** edetate disodium, phenol, sodium metabisulfite in water for injection. May also contain sodium hydroxide and/or sulfuric acid for pH adjustment.

##### **Tobramycin for Injection:**

**Medical ingredients:** Tobramycin supplied as Tobramycin sulfate

**Non-medical ingredients:** None

#### **Tobramycin Injection, USP and Tobramycin for Injection, USP come in the following dosage forms:**

##### **Tobramycin Injection, USP:**

- Liquid for Injection - 10 mg / mL and 40 mg / mL

##### **Tobramycin for Injection, USP:**

- Powder for Injection – 1.2g / vial

#### **Do not use Tobramycin Injection, USP and Tobramycin for Injection, USP if:**

- you are allergic to tobramycin or any ingredients in the drug (See what are the ingredients in Tobramycin Injection, USP and Tobramycin for Injection, USP).
- you are allergic to other aminoglycosides.

**To help avoid side effects and ensure proper use, talk to your healthcare professional before you take Tobramycin Injection, USP or Tobramycin for Injection, USP. Talk about any health conditions or problems you may have, including if you:**

- have drug allergies.
- have hearing or balance problems.
- have kidney problems.
- have Myasthenia gravis (a muscle condition).
- have Parkinson's Disease.
- are pregnant or planning to become pregnant.
- are breastfeeding or planning to breastfeed

**Other warnings you should know about:**

Tobramycin Injection, USP, Tobramycin for Injection, USP and other similar aminoglycosides have been known to cause hearing and balance problems and kidney problems. Your doctor will observe you carefully for warning signs of these events after giving you Tobramycin Injection, USP or Tobramycin for Injection, USP.

Your doctor may monitor the level of Tobramycin Injection, USP and Tobramycin for Injection, USP in your blood through blood tests, especially if you are taking, or have taken in the recent past, certain medications that can interact with tobramycin.

**Tell your healthcare professional about all the medicines you take, or have taken in the recent past, including any drugs (prescription and non-prescription), vitamins, minerals, natural supplements or alternative medicines.**

**The following may interact with Tobramycin Injection, USP and Tobramycin for Injection, USP:**

- aminoglycosides (e.g. amikacin, streptomycin, neomycin, kanamycin, gentamicin, and paromomycin)
- amphotericin B
- cephaloridine
- cisplatin
- colistin
- decamethonium
- diuretics (specifically potent diuretics)
- polymyxin B
- succinylcholine
- tubocurarine
- vancomycin
- viomycin

**How to take Tobramycin Injection, USP and Tobramycin for Injection, USP:**

Tobramycin Injection, USP and Tobramycin for Injection, USP are for intramuscular injection or intravenous infusion after dilution. The usual intravenous infusion time is 20 to 60 minutes.

Tobramycin Injection, USP and Tobramycin for Injection, USP will be given to you by a doctor or nurse in a hospital or clinical setting.

**Usual dose:**

Your doctor will give you the most appropriate dose based on your age, weight, the type of infection you have, and any medical conditions you may have.

You may receive Tobramycin Injection, USP or Tobramycin for Injection, USP several times a day over a period of 7 to 10 days. Your doctor may decide to give it to you for a longer period depending on the type and severity of your bacterial infection.

**Overdose:**

If you think you have taken too much Tobramycin Injection, USP or Tobramycin for Injection, USP, contact your healthcare professional, hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms.

**Missed Dose:**

If you have missed a dose of medication, contact your healthcare professional.

**What are possible side effects from using Tobramycin Injection, USP and Tobramycin for Injection, USP?**

These are not all the possible side effects you may feel when taking Tobramycin. If you experience any side effects not listed here, contact your healthcare professional.

Stop taking Tobramycin Injection, USP and Tobramycin for Injection, USP and contact your doctor if:

a) you have symptoms of an allergic reaction such as:

- rash, hives, itching or skin irritation.
- reaction at the injection site.

b) you have severe diarrhea (bloody or watery) with or without:

- fever
- stomach pain or tenderness

You may have Clostridium difficile colitis (bowel inflammation). See your doctor right away.

Other side effects include:

- diarrhea
- fever
- headache
- nausea
- tiredness
- vomiting

If you have troublesome symptom or side effect that is not listed here or becomes bad enough to interfere with your daily activities, talk to your healthcare professional.

### Reporting Side Effects

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (<https://www.canada.ca/en/health-canada/services/drugs-health-products/medeffect-canada/adverse-reaction-reporting.html>) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345.

*NOTE:* Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.

### Storage

Store in the original container between 15°C and 30°C.

Keep out of reach and sight of children.

### If you want more information about Tobramycin Injection, USP and Tobramycin for Injection, USP:

- Talk to your healthcare professional
- Find the full product monograph that is prepared for healthcare professionals and includes this Patient Medication Information by visiting the Health Canada website (<https://www.canada.ca/en/health-canada.html>); Fresenius Kabi Canada's website (<https://www.fresenius-kabi.com/en-ca/>), or by calling 1-877-821-7724.
