PRODUCT MONOGRAPH

VANCOMYCIN HYDROCHLORIDE FOR INJECTION, USP

ANTIBiotic

Fresenius Kabi Canada Ltd.
45 Vogell Rd, Suite 200
Richmond Hill, ON L4B 3P6

Date of Preparation: February 17, 2015

Control No.: 181577
NAME OF DRUG

VANCOMYCIN HYDROCHLORIDE FOR INJECTION, USP

THERAPEUTIC CLASSIFICATION

Antibiotic

ACTIONS

The inhibition of cell wall synthesis has been shown by in vitro studies to be responsible for the bactericidal action of vancomycin against many gram-positive bacteria. There is also evidence that RNA synthesis is selectively inhibited and the permeability of the cell membrane is altered by vancomycin.

INDICATIONS AND CLINICAL USES

Vancomycin Hydrochloride for Injection, USP is indicated in the therapy of severe or life-threatening staphylococcal infections in patients who cannot receive or have failed to respond to the penicillins or cephalosporins, or who have infections with staphylococci resistant to other antibiotics, including methicillin.

In the treatment of staphylococcal endocarditis, vancomycin has been used successfully alone.

In other infections due to staphylococci, including osteomyelitis, pneumonia, septicemia and soft-tissue infections, vancomycin's effectiveness has been documented. Antibiotics are used as adjuncts to appropriate surgical measures when staphylococcal infections are localized and purulent.

Although no controlled clinical efficacy trials have been conducted, intravenous vancomycin has been suggested by the American Heart Association and the American Dental Association as prophylaxis against bacterial endocarditis in patients allergic to penicillin who have congenital and/or rheumatic or other acquired valvular heart disease when they undergo dental procedures or surgical procedures of the upper respiratory tract. (Note: When selecting antibiotics for the prevention of bacterial endocarditis, the
physician or dentist should read the full joint statement of the American Heart Association and the American Dental Association.)

For the treatment of staphylococcal enterocolitis and antibiotic-associated pseudomembranous colitis produced by *Clostridium difficile*, vancomycin should be used orally. Parenteral administration of vancomycin is not effective for these indications, therefore vancomycin must be given orally. For the treatment of other types of infection vancomycin is not effective by the oral route.

Specimens for bacteriological cultures should be obtained in order to isolate and identify the causative organisms and to determine their susceptibility to vancomycin.

**CONTRAINDICATIONS**

Vancomycin Hydrochloride for Injection, USP is contraindicated in patients with known hypersensitivity to the antibiotic.

**WARNINGS**

Exaggerated hypotension, including shock, and rarely cardiac arrest may result from rapid bolus administration (e.g., over several minutes) of vancomycin hydrochloride.

Toxic serum levels can occur when given intravenously. Vancomycin is excreted fairly rapidly by the kidney and with decreased renal clearance, blood levels increase markedly. The risk of toxicity appears appreciably increased by high blood concentrations or prolonged treatment during parenteral therapy. Orally, vancomycin is poorly absorbed. Therefore, toxic serum levels are not attained from oral dosage.

When serum levels exceed 80 µg/mL, ototoxicity has occurred. Tinnitus may precede deafness. The elderly are more likely to experience auditory damage. Deafness may be progressive despite cessation of treatment, as experience with other antibiotics suggests.
Careful monitoring is required with concurrent and sequential use of other neurotoxic and/or nephrotoxic agents, particularly aminoglycoside antibiotics, cephaloridine, polymixin B, colistin, viomycin, paromomycin, cisplatin and neuromuscular blocking agents.

If parenteral and oral vancomycin are administered concomitantly, an additive effect may occur, which should be considered when calculating the total dose given. Levels of vancomycin in serum should be monitored in these circumstances.

**PRECAUTIONS**

To avoid rapid infusion-related reactions, Vancomycin Hydrochloride for Injection, USP should be administered in a dilute solution over a period of not less than 60 minutes. A prompt cessation of these reactions usually results when the infusion is stopped (see DOSAGE AND ADMINISTRATION and ADVERSE REACTIONS).

Vancomycin hydrochloride should be used with care in patients with renal insufficiency because of its ototoxicity and nephrotoxicity. The dose and/or dose intervals should be adjusted carefully and blood levels monitored if it is necessary to use vancomycin parenterally in patients with renal impairment.

In patients with previous hearing loss, vancomycin should be avoided (if possible). If used in such patients, the dose of vancomycin should be monitored by periodic determination of drug levels in blood. Serial tests of auditory function and of vancomycin blood levels should be performed in patients with renal insufficiency and in individuals over the age of 60. Periodic hematologic studies, urinalyses and liver and renal function tests should be taken in all patients receiving vancomycin.

The overgrowth of non-susceptible organisms may result with the use of vancomycin. Appropriate measures should be taken if new infections due to bacteria or fungi appear during therapy with this product. These measures should include the withdrawal of vancomycin.

In rare instances, there have been reports of pseudomembranous colitis due to *C. difficile* developing in patients who received intravenous vancomycin.
**Vancomycin should never be given intramuscularly.** Vancomycin is irritating to tissue and causes drug fever, pain and possibly necrosis if injected intramuscularly. Therefore, it must be administered intravenously. In many patients receiving vancomycin, pain and thrombophlebitis occur and are occasionally severe. By administering the drug in a volume of at least 200 mL of glucose or saline solution and by rotating the sites of injection, the frequency and severity of thrombophlebitis can be minimized.

The frequency of infusion-related events (including hypotension, flushing, erythema, urticaria and pruritus) has been reported to increase with concomitant administration of anesthetic agents. The administration of vancomycin hydrochloride as a 60-minute infusion prior to anesthetic induction may minimize infusion-related events.

The safety and efficacy of administering vancomycin by the intrathecal (intralumbar or intraventricular) route have not been assessed.

Some patients with inflammatory disorders of the intestinal mucosa may have significant systemic absorption of oral vancomycin and may thus be at risk of developing adverse reactions associated with parenteral administration of vancomycin. This risk is greater in the presence of renal impairment. Total systemic and renal clearance of vancomycin are reduced in the elderly.

When patients with underlying renal dysfunction or those receiving concomitant therapy with an aminoglycoside are being treated, serial monitoring of renal function should be performed.

**Use in Pregnancy**
Vancomycin should be given during pregnancy only if clearly needed. Vancomycin levels of 13.2, and 16.7 µg/mL were measured in cord blood of 2/10 pregnant women treated with vancomycin in a controlled clinical study of serious staphylococcal infection complicating intravenous drug abuse. Because the number of patients treated in this study was small and vancomycin administered only in the second and third trimesters, it is not known whether vancomycin causes fetal harm.

**Nursing Mothers**
Vancomycin is excreted in human milk. Caution should be exercised if vancomycin is administered to a nursing mother. The potential for adverse effects warrants that a decision be made whether to discontinue
nursing of the infant or administration of vancomycin, taking into account the importance of the drug to the nursing mother.

**Pediatrics**

In premature neonates and in young infants, it may be advisable to confirm desired serum levels of vancomycin.

Concomitant administration of vancomycin and anesthetic agents has been associated with erythema and histamine-like flushing in children.

**Geriatrics**

Vancomycin dosage levels should be adjusted in elderly patients. The natural decrease in glomerular filtration rate with increasing age may lead to elevated concentrations of vancomycin in serum if dosages are not adjusted.

**Burn Patients**

Burn patients reportedly have higher total body clearance rates for vancomycin and may thus require more frequent and higher doses. Dosage individualisation and close monitoring of burn patients being treated with vancomycin may be warranted.

**ADVERSE REACTIONS**

**Infusion-Related Events**

Associated with the administration of vancomycin hydrochloride are nausea, chills, fever, wheezing, dyspnea, pruritis, urticaria and macular rashes. Eosinophilia and anaphylactoid reactions may also be produced. A throbbing type of pain in the muscles of the back and neck has been described and can usually be minimized or avoided by slower administration (see **DOSAGE AND ADMINISTRATION**). There have been reports of hypotension which is more apt to occur with rapid administration. During rapid administration flushing of the skin over the neck and shoulder with transitory fine rash including urticaria ("red neck") has also been observed. These reactions may persist for several hours but usually resolve within 20 - 30 minutes.
**Nephrotoxicity**
Renal failure has been reported rarely in patients treated with vancomycin, principally manifested by increased serum creatinine or BUN, particularly in patients given large doses. Most of these have occurred in patients who had pre-existing kidney dysfunction or who were given aminoglycosides concomitantly. Azotemia resolved in most patients upon discontinuance of vancomycin. Rare cases of interstitial nephritis have been reported in patients treated with vancomycin.

**Ototoxicity**
Hearing loss associated with vancomycin has been reported by approximately two dozen patients. In most cases, patients also had kidney dysfunction, pre-existing hearing loss or concomitant treatment with an ototoxic drug. Rarely have there been reports of vertigo, dizziness and tinnitus.

**Hematopoietic**
The development of reversible neutropenia, usually starting one week or more after onset of therapy with vancomycin or after a total dose of more than 25 g has been reported, including some 24 "spontaneous cases" from published reports and other sources. Upon discontinuance of vancomycin, neutropenia appears to be promptly reversible. Thrombocytopenia has been reported rarely. Reversible agranulocytosis (granulocyte count less than 5000/mm³) has been reported rarely.

**Phlebitis**
Inflammation at the injection site has been reported.

**Miscellaneous**
Drug fever, exfoliative dermatitis, Stevens-Johnson syndrome, and rare cases of vasculitis have been associated with the administration of vancomycin.

**TREATMENT OF OVERDOSAGE**

For management of a suspected drug overdose, contact your regional Poison Control Centre.

Hemofiltration and hemoperfusion with polysulfone resins reportedly result in increased clearance of vancomycin. As no specific antidote is known, general supportive treatment is indicated. Significant amounts of vancomycin are not removed by dialysis.
DOSAGE AND ADMINISTRATION

Each dose should be administered at a rate of no more than 10 mg/min or over a period of at least 60 minutes.

Intravenous Dosage

Adults:
The usual intravenous dose is 500 mg every 6 hours or 1 g every 12 hours. Other patient factors such as age or obesity may call for modification of the usual intravenous daily dose.

Adults with Impaired Renal Function:
To avoid toxic serum levels dosage adjustment is required in patients with impaired renal function. Since accumulation in such patients has been reported to occur over several weeks of treatment, serum levels should be checked regularly.

The dosage calculation may be made by using the following nomogram if the creatinine clearance value is known for most patients with renal impairment or the elderly:

(Moellering et al. 1981)
For functionally anephric patients on dialysis, the nomogram is not valid. In order to achieve therapeutic serum levels promptly in such patients, a loading dose of 15 mg/kg of body weight should be given. The dose required to maintain stable serum levels is 1.9 mg/kg/24 h.

When only serum creatinine is available, the conversion of this value into estimated creatinine clearance may be accomplished by using the following formula based on sex, weight and age of the patient.

A steady state of renal function is represented by the serum creatinine.

| Males: | \( \frac{\text{Weight (kg) x (140 - age)} \times 72}{\text{serum creatinine}} \) |
| Females: | 0.85 x above value |

**Neonates, Infants and Children:**
The dosage schedule which follows has been used. Infusions can be divided and incorporated in the child's 24-hour fluid requirement and should be infused over 60 minutes.

**Infants and Neonates:** It is suggested that an initial dose of 15 mg/kg be administered followed by 10 mg/kg every twelve hours for neonates in the first week of life and every eight hours thereafter up to the age of one month. Each dose should be given over 60 minutes. Close monitoring of serum concentrations of vancomycin may be warranted in these patients.

**Children:** The usual i.v. dosage of vancomycin is 10 mg/kg given every six hours.

The majority of patients with infections caused by organisms susceptible to the antibiotic demonstrate a therapeutic response by 48 to 72 hours. The total duration of therapy is determined by the type and severity of the infection and the clinical response of the patient. In staphylococcal endocarditis, therapy for three weeks or longer is recommended.

**Oral Dose**
*Vancomycin, when administered orally, is to be used only in the treatment of staphylococcal enterocolitis, and/or pseudomembranous colitis associated with toxigenic Clostridium difficile.*
**Adults:**
The usual daily dose for antibiotic-associated colitis and/or staphylococcal enterocolitis is 125 - 500 mg. orally every 6 - 8 hours for 7 - 10 days.

**Children:**
The usual daily dosage is approximately 40 mg/kg in 3 or 4 divided doses for 7 - 10 days. The total daily dose should not exceed 2 g.

**Administration**

**Intermittent Intravenous Infusion:**
It is necessary to **further dilute** the reconstituted solution with 100 - 200 mL Normal Saline or D5W (dextrose in sterile water for injection). The infusion should be over a period of at least 60 minutes. See the **RECONSTITUTION** section for instruction.

**Continuous Intravenous Infusion:**
Only when intermittent infusion is not practical should continuous intravenous infusion be used. A concentration no greater than 10 mg/mL is recommended. An infusion of 10 mg/min or less is associated with fewer infusion-related adverse events.

**Oral Administration:**
By diluting the contents of the i.v. vial (500 mg) in 30 mL of water, the patient is permitted to drink the antibiotic or the solution may be administered via nasogastric tube.
PHARMACEUTICAL INFORMATION

Drug Substance

Proper Name: vancomycin hydrochloride

Chemical Name:

Structure:

Molecular Formula: \(\text{C}_{66}\text{H}_{75}\text{Cl}_{12}\text{N}_{9}\text{O}_{24} \cdot \text{HCl}\)

Molecular Weight: 1485.68

Description:
Vancomycin hydrochloride is an off-white to light-tan lyophilized plug. It forms a clear, colourless solution with a pH range of 2.5 to 4.5 when reconstituted in water.
COMPOSITION
Each vial contains vancomycin hydrochloride equivalent to 500 mg, 1 g, 5 g and 10 g vancomycin base.

STABILITY AND STORAGE RECOMMENDATIONS
Store the unreconstituted product between 15 °C and 30 °C.

RECONSTITUTION
500 mg vial: The addition of 10 mL of Sterile Water for Injection provides a reconstituted solution containing approximate average vancomycin concentration of 50 mg/mL.

1 g vial: The addition of 20 mL of Sterile Water for Injection provides a reconstituted solution containing approximate average vancomycin concentration of 50 mg/mL.

5 g vial: The addition of 100 mL of Sterile Water for Injection provides a reconstituted solution containing approximate average vancomycin concentration of 50 mg/mL.

Note: Further dilution is required.

10 g vial: The addition of 95 mL of Sterile Water for Injection provides a reconstituted solution containing approximate average vancomycin concentration of 100 mg/mL.

Note: Further dilution is required.

For Intermittent Intravenous Infusion

500 mg vial: Dilution of reconstituted solutions is required using at least 100 mL of 0.9% Sodium Chloride Injection or 5% Dextrose in Sterile Water for Injection.

1 g vial: Dilution of reconstituted solutions is required using at least 200 mL of 0.9% Sodium Chloride Injection or 5% Dextrose in Sterile Water for Injection.

5 g vial: Further dilution of the reconstituted solution is required. The 5 g vial is a Pharmacy Bulk Package intended for pharmacy use only.

10 g vial: Further dilution of the reconstituted solution is required. The 10 g vial is a Pharmacy Bulk Package intended for pharmacy use only.
For Continuous Intravenous Infusion
The vial contents are first reconstituted by adding Sterile Water for Injection as follows:

500 mg vial: add 10 mL of Sterile Water for Injection
1 g vial: add 20 mL of Sterile Water for Injection

The reconstituted solution is then added to one of the following i.v. solutions:
- 5% Dextrose Injection
- 5% Dextrose and 0.9% Sodium Chloride Injection
- 0.9% Sodium Chloride Injection

As with all parenteral drug products, intravenous admixtures should be inspected visually for clarity, particulate matter, precipitate, discoloration and leakage prior to administration whenever solution and container permit. Solutions showing haziness, particulate matter, precipitate, discoloration or leakage should not be used. Single-dose vials. Discard unused portion.

Pharmacy Bulk Package
The availability of the Pharmacy Bulk Package is restricted to hospitals with a recognized intravenous admixture program.

Directions for Dispensing from Maxivials (Pharmacy Bulk Package):
Vancomycin Hydrochloride for Injection, USP is available in a single use vial for pharmacy use only, referred to as a Maxivial®. Like the single-dose vial, Maxivial® is not for direct infusion. Maxivial® comes with a hanging vial label and should be suspended as a unit in a laminar flow hood. Entry into the vial must be made with a sterile dispensing device and contents dispensed in aliquots using aseptic technique (see DOSAGE AND ADMINISTRATION). Use of syringe/needle is not recommended as it may cause leakage. Any unused portion of the reconstituted stock solution should be discarded within 8 hours after initial entry.

STABILITY OF SOLUTIONS
Storage
If stored at room temperature, reconstituted solutions and further diluted infusion mixtures should be used within 24 hours. However, if stored under refrigeration (4 °C), they should be used within 96 hours.
**Incompatibility**

The following are some of the specific substances found to be incompatible: aminophylline, amobarbital sodium, chloramphenicol sodium succinate, chlorothiazide sodium, dexamethasone sodium phosphate, methicillin sodium, vitamin B complex with C, heparin sodium, penicillin G potassium, phenobarbital sodium, phenytoin sodium, secobarbital sodium, sodium bicarbonate and warfarin sodium.

**AVAILABILITY OF DOSAGE FORMS**

Vancomycin Hydrochloride for Injection, USP is available as a sterile lyophilized powder as follows:

- **500 mg** 10 mL single-dose vials containing vancomycin hydrochloride equivalent to 500 mg vancomycin base. Flip-top vials in packages of 10 or 25.
- **1 g** 20 mL single-dose vials containing vancomycin hydrochloride equivalent to 1 g vancomycin base. Flip-top vials in packages of 10.

**Pharmacy Bulk Packages:**

- **5 g** 100 mL single use vials containing vancomycin hydrochloride equivalent to 5 g vancomycin base. Flip-top vial individually packaged.
- **10 g** 100 mL single use vials containing vancomycin hydrochloride equivalent to 10 g vancomycin base. Flip-top vial individually packaged.

**MICROBIOLOGY**

Vancomycin hydrochloride has not demonstrated cross-resistance with other classes of antibiotics. A slow, stepwise laboratory-induced resistance has been reported to occur. Neither changes in pH nor the presence of serum significantly alter vancomycin's activity. Most strains of the following organisms are sensitive *in vitro* and in clinical infections to vancomycin:

*Staphylococcus aureus* (including heterogenous methicillin-resistant strains)

*Clostridium difficile*

*S. epidermidis* (including heterogenous methicillin-resistant strains)

*Streptococcus pneumoniae* (including multiple-resistant strains)

*S. pyogenes* (group A beta-hemolytic)

*S. agalactiae* (group B beta-hemolytic)
S. bovis
Alpha-hemolytic streptococci (viridans groups)
Enterococci (e.g., S. faecalis)
Bacillus sp.
Listeria monocytogenes
Lactobacillus sp.
Neisseria sp.
Diphtheroids
Actinomyces sp.

Note: In vitro, many strains of streptococci, staphylococci, C. difficile and other gram-positive bacteria are susceptible to concentrations of 0.5 to 5 µg/mL. A small proportion of S. aureus strains requires 10 to 20 µg/mL for inhibition whereas staphylococci are generally susceptible to less than 5 µg/mL of vancomycin hydrochloride. In vivo and in vitro resistance to vancomycin has been reported in clinically significant coagulase negative staphylococci identified as S. hemolyticus.

Enterococci of various species resistant to vancomycin and related glycopeptide antibiotics have been isolated from hospitalised patients in France, UK, and in the USA. Transfer of resistance to E. faecium, or E. fecalis, and to Streptococcus sanguis has also been documented.

In vitro, vancomycin is not effective against gram-negative bacilli, mycobacteria or fungi.

**Methods of Susceptibility Testing**

A 30 µg disc of vancomycin should produce a zone of more than 11 mm when in contact with "susceptible" organisms when the standardized method of disc susceptibility testing is used. Intermediate susceptibility is indicated by a zone size of 10 - 11 mm and resistance is indicated by a zone size of 9 mm or less.

Susceptibility to vancomycin is indicated by an MIC of ≤ 5 µg/mL with the WHO-ICS agar dilution and broth dilution methods.

**Assay Methods**

Bennett's agar-well diffusion method, which can quantitatively measure vancomycin concentrations from 0.5 to 8 µg/mL, can be used to determine vancomycin serum and tissue levels.

Two disc-diffusion assay methods, both using *Bacillus subtilis* as the test organism, are available for vancomycin. Antibiotic medium No. 5 is used in the first method which is capable of measuring vancomycin levels from approximately 5 to 40 µg/mL. Vancomycin concentrations from about 0.8 to 25 µg/mL can be detected with the second method which uses minimal salt agar. A reliable bioassay for vancomycin (in concentrations of 0.78 to 50.0 µg/mL) in the presence of rifampin or aminoglycosides is permitted with modification of the latter assay. An automated fluorescence polarization immunoassay and a radio-immunoassay are two available commercially prepared assay methods.
PHARMACOLOGY

Human Pharmacology
Adults:
Intravenous Administration
Multiple 500 mg dosages infused over 30 minutes every 6 hours gave peak concentrations ranging from 41 - 57 µg/mL. Mean peak plasma concentrations were 64 µg/mL immediately post infusion, 12.5 µg/mL at 6 hours and 7 µg/L at 12 hours post infusion following multiple 60 minute 1 g i.v. infusions of vancomycin in healthy volunteers.

A single i.v. injection of 1 g infused over a period of 30 minutes produced peak levels of 85 µg/mL after 2 hours, 11 µg/mL at 6 hours, and 5.1 µg/mL at 12 hours. A single injection of 500 mg resulted in mean serum concentrations of 51 µg/mL, with levels of 18.6 µg/mL, and 5.8 µg/mL at 6, and 12 hours respectively. Plasma half-life ranged from 3 - 8 hours with a mean of 4.5 hours.

Renal Insufficiency
Twenty-nine anephric patients were infused with 1 g of vancomycin in 250 mL of D5W over 30 minutes. The serum concentration was still 3.5 µg/mL after 18 days with intermittent dialysis at 3-day intervals. The half-life of elimination was about 7.5 days.
Figure 1. Elimination of vancomycin by anephric patients and by patients with normal renal function.

Figure 2. Elimination of vancomycin after a single 1-g i.v. dose by anephric patients undergoing hemodialysis at three-day intervals.

Table 2. Pharmacokinetic parameters of vancomycin in anephric and normal patients, as analyzed by two-compartment distribution.

* C_pO = peak concentration in serum; K_{21} and K_{12} = first-order rate constants for distribution of drug from tissue into plasma and from plasma into tissue, respectively; K_{el} = elimination rate constant; t_{1/2} (β) = elimination half-life; Cl = rate of drug clearance; Vd = apparent volume of distribution; Vc = volume of distribution in central compartment. Values given are means.

† This group was composed of patients with normal renal function.

(Cunha et al. 1981)

**Oral Administration**

Vancomycin is poorly absorbed after oral administration, only trace amounts are found in urine and blood. Following a dose of 125 mg orally four times daily, the mean concentration of vancomycin in stools was approximately 350 µg/g. After up to ten daily doses of 2 g, a mean level of 3100 µg/g (with a range of 905 - 8760 µg/g) was detected in feces of patients with pseudomembranous colitis.
Tissue Penetration and Distribution

Central Nervous System
Vancomycin does not readily diffuse across normal meninges into spinal fluid, but penetrates into spinal fluid when the meninges are inflamed.

Other Tissues and Fluids
Vancomycin concentrations in human bile, pleural, ascitic, pericardial, and synovial fluids reach approximately one-third of the equivalent serum level after single i.v. doses. A level of 7.6 µg/mL was achieved in the brain cyst of an infant following i.v. infusion of 40 mg/kg daily for 4 days.

Dogs died several days after drug administration, generally from kidney failure, while rats died quickly from CNS-mediated effects.

Vancomycin caused a slight dose-related drop in blood pressure when administered intravenously in a 5 percent solution to dogs at a rate of 0.6 mL/minute. Blood pressure dropped dramatically, as much as 40%, when the same dogs were given the same doses at a rate of 15 mL/minute. It is unknown, at present, whether the response is due to a direct effect on histamine receptors, or to the possible release of histamine from mast cells.
**Chronic Toxicity**

Vancomycin was given to dogs in daily doses of 12.5, 25 and 50 mg/kg for 21 - 311 days. Renal damage was seen in 4/22 dogs receiving 50 mg/kg/day.

Irritation at the injection site was the only toxic effect resulting from the daily i.v. administration of 25 or 50 mg/kg to monkeys for 16 to 187 days.

No evidence of systemic toxicity was seen in cats receiving daily i.m. doses of 25 and 50 mg/kg for 3 months.

Nine guinea pigs that received 100 mg vancomycin subcutaneously did not develop anaphylaxis when challenged 25 days later with a 25 mg i.v. dose.

Neither 150 mg vancomycin nor 60 mg tobramycin given alone to rats produced nephrotoxicity. However, significant renal toxicity occurred when administered together.

Ototoxicity was not produced in a guinea pig model administered 1000 mg/kg vancomycin and 40 mg/kg ethacrynic acid concurrently.

Neuromuscular blocking has not been demonstrated in rabbits treated with vancomycin.
